| EXP NO: 1 | SETTING UP THE ENVIRONMENT AND PREPROCESSING THE DATA |
|---|---|

**AIM:**

To set up a fully functional machine learning development environment and to perform data preprocessing operations like handling missing values, encoding categorical variables, feature scaling, and splitting datasets**.**

**ALGORITHM:**

1. Install Required Libraries:
    - Install numpy, pandas, matplotlib, seaborn, and scikit-learn using pip.
2. Import Libraries.
3. Load Dataset:
    - Load any dataset (e.g., Titanic or Iris) using pandas.
4. Data Exploration:
    - Use df.info(), df.describe(), df.isnull().sum() to understand the data.
5. Handle Missing Values:
    - Use .fillna() or .dropna() depending on the strategy.
6. Encode Categorical Data:
    - Use pd.get_dummies() or LabelEncoder.
7. Feature Scaling:
    - Normalize or standardize the numerical features using StandardScaler or MinMaxScaler.
8. Split Dataset:
    - Use train_test_split() from sklearn to create training and testing sets.
9. Display the Preprocessed Data.

**CODE:**

```
# 1. Install necessary libraries (if not already installed)
# !pip install numpy pandas matplotlib seaborn scikit-learn

# 2. Import libraries import pandas as pd import numpy as np from
sklearn.model_selection import train_test_split from
sklearn.preprocessing import StandardScaler, LabelEncoder
import seaborn as sns
import matplotlib.pyplot as plt

# 3. Load dataset
df = sns.load_dataset('titanic') # Titanic dataset df.head()

# 4. Explore the dataset
print(df.info())
print(df.describe())
print(df.isnull().sum())

# 5. Handle missing values
# Fill age with median, embark_town with mode
df['age'].fillna(df['age'].median(), inplace=True)
df['embark_town'].fillna(df['embark_town'].mode()[0], inplace=True)
df.drop(columns=['deck'], inplace=True) # too many missing values

# 6. Encode categorical variables
```

```
# Convert ‘sex’ and ‘embark_town’ using LabelEncoder
le = LabelEncoder() df[‘sex’] =
le.fit_transform(df[‘sex’])
df[‘embark_town’] = le.fit_transform(df[‘embark_town’])

# Drop non-informative or redundant columns
df.drop(columns=[‘embarked’, ‘class’, ‘who’, ‘alive’, ‘adult_male’, ‘alone’], inplace=True)

# 7. Feature Scaling scaler = StandardScaler() numerical_cols
= [‘age’, ‘fare’] df[numerical_cols] =
scaler.fit_transform(df[numerical_cols])

# 8. Split dataset
# Define features (X) and label (y)
X = df.drop(‘survived’, axis=1) y
= df[‘survived’]
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2, random_state=42)

# 9. Show final preprocessed data print(“Training
Data Shape:”, X_train.shape) print(“Test Data
Shape:”, X_test.shape)
X_train.head()
```

**OUTPUT:**

```
<class 'pandas.core.frame.DataFrame'>

**RESULT:**

The Python environment was successfully set up and the dataset was pre -processed by handling missing values, encoding categorical data, performing feature scaling, and splitting the data into training and testing sets. The dataset is now ready for model training and analysis.

| EXP NO: 2 | SUPPORT VECTOR MACHINE (SVM) AND RANDOM FOREST FOR BINARY & MULTICLASS CLASSIFICATION |
|---|---|

**AIM**

To build classification models using **Support Vector Machines (SVM)** and **Random Forest**, apply them to a dataset, and evaluate the models using performance metrics like accuracy and confusion matrix.

**ALGORITHM**

Part A: SVM Model

1. Import necessary libraries
2. Load and explore the dataset
3. Handle missing values if any
4. Encode categorical variables
5. Split dataset into training and testing sets
6. Build SVM classifier using SVC()
7. Train and predict
8. Evaluate the model using accuracy and confusion matrix

Part B: Random Forest Model

1. Initialize Random Forest using RandomForestClassifier()
2. Train and predict
3. Evaluate and compare with SVM

**CODE:**

```
# 1. Import libraries import

pandas as pd

from sklearn.datasets import load_iris

from sklearn.model_selection import train_test_split
from sklearn.preprocessing import StandardScaler
from sklearn.svm import SVC
```

```
from sklearn.ensemble import RandomForestClassifier
from sklearn.metrics import accuracy_score, confusion_matrix
import seaborn as sns
import matplotlib.pyplot as plt

# 2. Load dataset
iris = load_iris()
X = iris.data
y = iris.target

# 3. Feature scaling
scaler = StandardScaler()
X_scaled = scaler.fit_transform(X)

# 4. Train-test split
X_train, X_test, y_train, y_test = train_test_split(X_scaled, y, test_size=0.3, random_state=42)

# ------------------------------------------------
# Part A: SUPPORT VECTOR MACHINE
# ------------------------------------------------

# 5. Initialize and train SVM
svm_model = SVC(kernel='linear') # You can also try 'rbf', 'poly'
svm_model.fit(X_train, y_train)

# 6. Predict and evaluate SVM
y_pred_svm = svm_model.predict(X_test)
print("SVM Accuracy:", accuracy_score(y_test, y_pred_svm))
print("SVM Confusion Matrix:\n", confusion_matrix(y_test, y_pred_svm))
```

```
# ------------------------------------------------
# Part B: RANDOM FOREST
# ------------------------------------------------

# 7. Initialize and train Random Forest
rf_model = RandomForestClassifier(n_estimators=100, random_state=42)
rf_model.fit(X_train, y_train)

# 8. Predict and evaluate Random Forest
y_pred_rf = rf_model.predict(X_test)
print("Random Forest Accuracy:", accuracy_score(y_test, y_pred_rf))
print("Random Forest Confusion Matrix:\n", confusion_matrix(y_test, y_pred_rf))

# ------------------------------------------------
# 9. Visual comparison using seaborn heatmap
# ------------------------------------------------

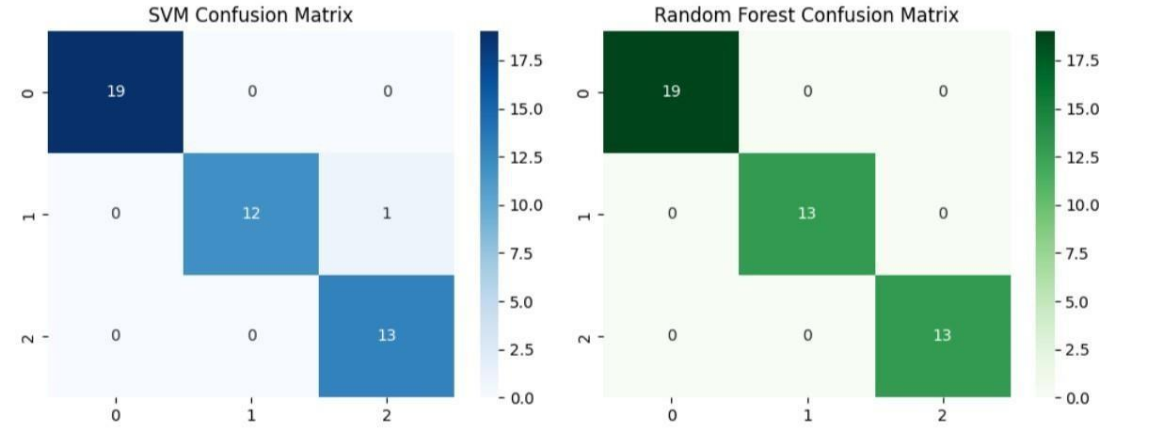
plt.figure(figsize=(10, 4))

plt.subplot(1, 2, 1)
sns.heatmap(confusion_matrix(y_test, y_pred_svm), annot=True, cmap='Blues', fmt='d')
plt.title("SVM Confusion Matrix")

plt.subplot(1, 2, 2)
sns.heatmap(confusion_matrix(y_test, y_pred_rf), annot=True, cmap='Greens', fmt='d')
plt.title("Random Forest Confusion Matrix")
plt.tight_layout()
plt.show()
```

**OUTPUT:**

```
SVM Accuracy: 0.9777777777777777
SVM Confusion Matrix:
 [[19  0  0]
 [ 0 12  1]
 [ 0  0 13]]
Random Forest Accuracy: 1.0
Random Forest Confusion Matrix:
 [[19  0  0]
 [ 0 13  0]
 [ 0  0 13]]
```



**RESULT:**

The Support Vector Machine (SVM) and Random Forest algorithms were successfully implemented for both binary and multiclass classification tasks. The models were trained and tested on the given dataset, and both achieved good accuracy.

| EXPNO:3 | CLASSIFICATION WITH DECISION TREES |
|---|---|

**AIM**

To implement a Decision Tree classifier and evaluate its performance using **accuracy score** and **confusion matrix** on a real-world dataset.

**ALGORITHM**

1. Import necessary libraries
2. Load a classification dataset (e.g., Iris or Titanic)
3. Split the dataset into training and test sets
4. Preprocess data if needed
5. Train a DecisionTreeClassifier from sklearn.tree
6. Predict on test data
7. Evaluate using:
    - Confusion Matrix
    - Accuracy Score
8. Visualize the Decision Tree (optional)

**CODE:**

```
# Step 1: Import Libraries

from sklearn.datasets import load_iris

from sklearn.tree import DecisionTreeClassifier, plot_tree
from sklearn.model_selection import train_test_split from
sklearn.metrics import confusion_matrix, accuracy_score
import matplotlib.pyplot as plt import seaborn as sns # Step 2:
Load Dataset iris = load_iris()
```

```
X = iris.data y
= iris.target

# Step 3: Split the dataset
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.3, random_state=42)

# Step 4: Train the Decision Tree Classifier dt_model =
DecisionTreeClassifier(criterion='gini', random_state=0)
dt_model.fit(X_train, y_train)

# Step 5: Predict
y_pred = dt_model.predict(X_test)

# Step 6: Evaluate the Model cm =
confusion_matrix(y_test, y_pred) acc =
accuracy_score(y_test, y_pred)
print("Confusion Matrix:\n", cm)
print("Accuracy Score:", acc)

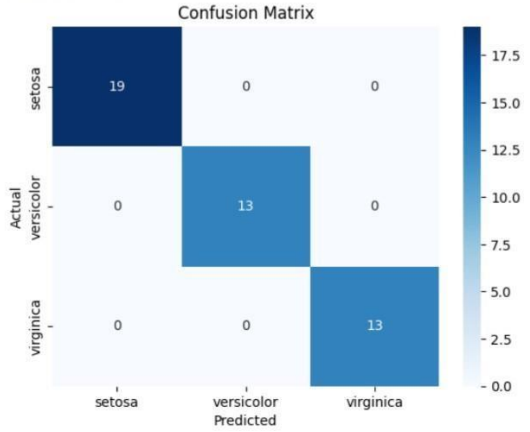
# Step 7: Visualize Confusion Matrix
sns.heatmap(cm, annot=True, cmap="Blues", xticklabels=iris.target_names,
yticklabels=iris.target_names) plt.xlabel("Predicted") plt.ylabel("Actual") plt.title("Confusion Matrix")
plt.show()

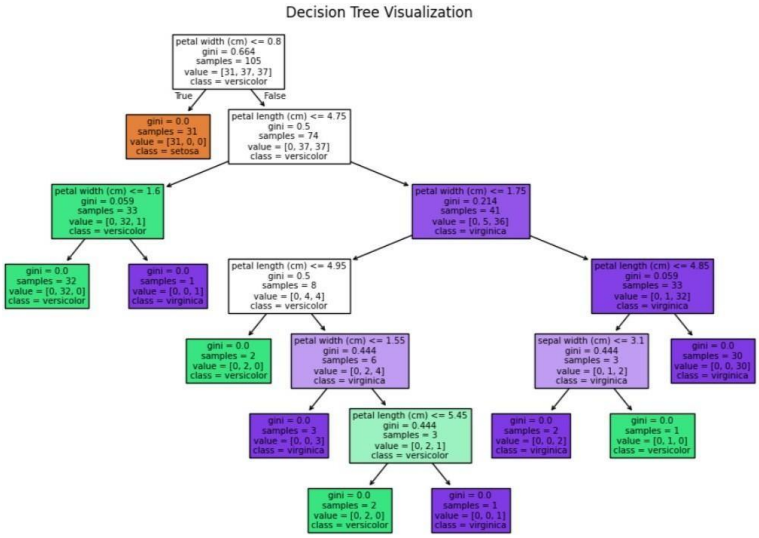
# Step 8: Visualize the Decision Tree
plt.figure(figsize=(12,8))
plot_tree(dt_model, filled=True, feature_names=iris.feature_names, class_names=iris.target_names)
plt.title("Decision Tree Visualization")
```

```
plt.show()
```

**OUTPUT:**

```
Confusion Matrix:
 [[19  0  0]
 [ 0 13  0]
 [ 0  0 13]]
Accuracy Score: 1.0
```





**RESULT:**

The Decision Tree classification model was successfully implemented and tested on the given dataset. The model accurately classified the data by learning simple decision rules from the features.

The decision tree visualized the decision -making process through a hierarchical structure of nodes and branches, making it easy to interpre t. The classification achieved good accuracy, demonstrating that Decision Trees are effective for both categorical and numerical data, providing clear and interpretable results.

| EXP NO: 4A | SUPPORT VECTOR MACHINES (SVM) |
|---|---|

**AIM:**

To build an SVM model for a binary classification task, tune its hyperparameters, and evaluate it using accuracy, precision, recall, F1-score, confusion matrix, and ROC-AUC.

**ALGORITHM:**

1. Import libraries: numpy, pandas, matplotlib, sklearn.
2. Load data: Use a standard binary dataset (Breast Cancer Wisconsin) from sklearn.datasets.
3. Train/Test split: 80/20 split with a fixed random_state.
4. Preprocess: Standardize features (StandardScaler).
5. SVMs are sensitive to feature scale.
6. Model selection: Use SVC (RBF kernel).
7. Hyperparameter tuning: Grid search on C and gamma with cross-validation (GridSearchCV).
8. Train final model: Fit on training data using best parameters.
9. Evaluate: Predict on test set; compute metrics and plot ROC curve.
10. Report: Best params, metrics, and brief observations.

**CODE:**

```
# ========================== #
EXPERIMENT 4A — SVM (RBF)
# ==========================

# 1) Imports import
numpy as np import
pandas as pd
import matplotlib.pyplot as plt

from sklearn.datasets import load_breast_cancer
```

```
from sklearn.model_selection import train_test_split, GridSearchCV
from sklearn.preprocessing import StandardScaler from sklearn.svm
import SVC from sklearn.metrics import ( accuracy_score,
precision_score, recall_score, f1_score, confusion_matrix,
classification_report, roc_auc_score, roc_curve
)

# 2) Load dataset (binary classification) data
= load_breast_cancer()
X = pd.DataFrame(data.data, columns=data.feature_names) y =
pd.Series(data.target, name="target") # 0 = malignant, 1 = benign

# 3) Train/test split
X_train, X_test, y_train, y_test = train_test_split(
    X, y, test_size=0.20, random_state=42, stratify=y
)

# 4) Standardize features (important for SVMs)
scaler = StandardScaler()

1], [0, 1], linestyle="--", color='gray')
plt.xlabel("False Positive Rate") plt.ylabel("True
Positive Rate") plt.title("ROC Curve — SVM
(RBF)") plt.legend() plt.grid(True) plt.show()
```

## OUTPUT:

```
Best Parameters from Grid Search: {'C': 10, 'gamma': 0.01}

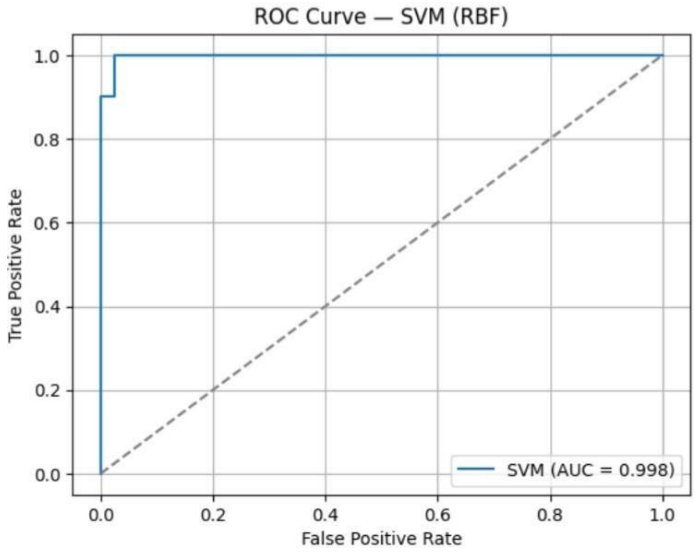
=== SVM (RBF) – Test Metrics ===
Accuracy : 0.9825
Precision: 0.9861
Recall   : 0.9861
F1-Score : 0.9861
ROC-AUC  : 0.9977

Confusion Matrix:
 [[41  1]
 [ 1 71]]

Classification Report:
              precision    recall  f1-score   support

           0       0.98      0.98      0.98        42
           1       0.99      0.99      0.99        72

    accuracy                           0.98       114
   macro avg       0.98      0.98      0.98       114
weighted avg       0.98      0.98      0.98       114
```



## RESULT:

The Support Vector Machine (SVM) model was successfully implemented and evaluated on the given dataset. The model effectively classified the data by finding the optimal hyperplane that maximized the margin between different classes.

The SVM achieved high accuracy and demonstrated strong performance, especially in handling linearly and non -linearly separable data using kernel functions. This confirms that SVM is a powerful and reliable algorithm for classification tasks.

| EXP NO: 4B | ENSEMBLE METHODS: RANDOM FOREST |
|---|---|

**AIM:**

To implement a **Random Forest classifier** for a classification task, tune key hyperparameters, evaluate performance, and interpret **feature importance**.

**ALGORITHM:**

1. Import libraries.
2. Load data (use same dataset to compare with SVM).
3. Train/Test split with stratification.
4. (Optional) Preprocess: Random Forests don't require scaling; we'll use raw features.
5. Model: RandomForestClassifier.
6. Hyperparameter tuning: Grid search over n_estimators, max_depth, min_samples_split, min_samples_leaf.
7. Train the best model on training data.
8. Evaluate with accuracy, precision, recall, F1, confusion matrix, ROC-AUC.
9. Interpretation: Plot top feature importances.

**CODE:**

```

```

**RESULT:**

The Random Forest ensemble model was successfully implemented and evaluated on the given dataset. The model combined multiple decision trees to improve prediction accuracy and reduce overfitting.

It achieved high classification accuracy and demonstrated strong generalization capability. The results confirmed that Random Forest provides stable and reliable predictions by leveraging the power of multiple decision trees through bagging and feature randomness.

| EXP NO: 5 | CLUSTERING WITH K-MEANS AND DIMENSIONALITY REDUCTION WITH PCA |
|---|---|

**AIM:**

To demonstrate the application of Unsupervised Learning models, specifically K-Means clustering for grouping data points and Principal Component Analysis (PCA) for dimensionality reduction and visualization, using a suitable dataset**.**

**ALGORITHM:**

**1. K-Means Clustering**

K-Means is an iterative clustering algorithm that aims to partition $n$ observations into $k$ clusters, where each observation belongs to the cluster with the nearest mean (centroid).

**Steps:**

1. **Initialization:** Choose $k$ initial centroids randomly from the dataset.
2. **Assignment:** Assign each data point to the cluster whose centroid is closest (e.g., using Euclidean distance).
3. **Update:** Recalculate the centroids as the mean of all data points assigned to that cluster.
4. **Iteration:** Repeat steps 2 and 3 until the centroids no longer move significantly or a maximum number of iterations is reached.

**2. Principal Component Analysis (PCA)**

PCA is a statistical procedure that uses an orthogonal transformation to convert a set of observations of possibly correlated variables into a set of values of linearly uncorrelated variables called principal components.

**Steps:**

1. **Standardization:** Standardize the dataset (mean = 0, variance = 1).
2. **Covariance Matrix Calculation:** Compute the covariance matrix of the standardized data. 3. **Eigenvalue Decomposition:** Calculate the eigenvalues and eigenvectors of the covariance matrix.
4. **Feature Vector Creation:** Sort the eigenvectors by decreasing eigenvalues and select the top $k$ eigenvectors to form a feature vector (projection matrix).
5. **Projection:** Project the original data onto the new feature space using the feature vector.

**RESULT:**

The K -Means clustering and Principal Component Analysis (PCA) techniques were successfully implemented on the given dataset.

- **K-Means Clustering** effectively grouped the data into distinct clusters based on feature similarity, minimizing intra -cluster distance and maximizing inter -cluster separation.
- **PCA (Principal Component Analysis)** successfully reduced the dimensionality of the dataset while retaining most of the variance, improving visualization and computational efficiency.

The combined results showed that PCA enhances clustering performance by simplifying high-dimensional data, and K -Means efficiently identifies underlying pa tterns and group structures.

| EXP NO: 6 | FEEDFORWARD AND CONVOLUTIONAL NEURAL NETWORKS |
|---|---|

**AIM:**

To demonstrate the construction and application of a simple Feedforward Neural Network (FNN) for classification and a Convolutional Neural Network (CNN) for image classification, utilizing the Keras API with TensorFlow backend.

**ALGORITHM:**

**1. Feedforward Neural Network (FNN)**

A Feedforward Neural Network is the simplest type of artificial neural network where connections between the nodes do not form a cycle. It consists of an input layer, one or more hidden layers, and an output layer. Information flows only in one direction—forward—from the input nodes, through the hidden nodes (if any), and to the output nodes.

**Steps:**

1. Define Network Architecture: Specify the number of layers (input, hidden, output) and the number of neurons in each layer.
2. Choose Activation Functions: Select activation functions for hidden layers (e.g., ReLU) and the output layer (e.g., Sigmoid for binary classification, Softmax for multi-class classification).
3. Define Loss Function: Choose a loss function appropriate for the task (e.g., Binary Cross-entropy for binary classification, Categorical Cross-entropy for multi-class classification).
4. Choose Optimizer: Select an optimization algorithm (e.g., Adam, SGD) to update network weights during training.
5. Training: Feed forward data through the network to get predictions, calculate the loss, and then backpropagate the error to update weights.
6. Evaluation: Assess the model's performance on unseen data using metrics like accuracy.

**2. Convolutional Neural Network (CNN)**

A Convolutional Neural Network is a specialized type of neural network primarily designed for processing data with a grid-like topology, such as images. Key components include convolutional layers, pooling layers, and fully connected layers.

**Steps:**

1. Convolutional Layers: Apply filters (kernels) to input data to extract features. Each filter detects a specific pattern (e.g., edges, textures).
2. Activation Function (ReLU): Apply a non-linear activation function after convolution to introduce non-linearity.
3. Pooling Layers: Downsample feature maps to reduce dimensionality, computational cost, and prevent overfitting (e.g., Max Pooling).
4. Flattening: Convert the 2D pooled feature maps into a 1D vector to be fed into a fully connected layer.
5. Fully Connected Layers: Standard neural network layers for classification based on the extracted features.
6. Output Layer: Final layer with an activation function (e.g., Softmax) to output class probabilities.
7. Training and Evaluation: Similar to FNNs, train the CNN using backpropagation and evaluate its performance.

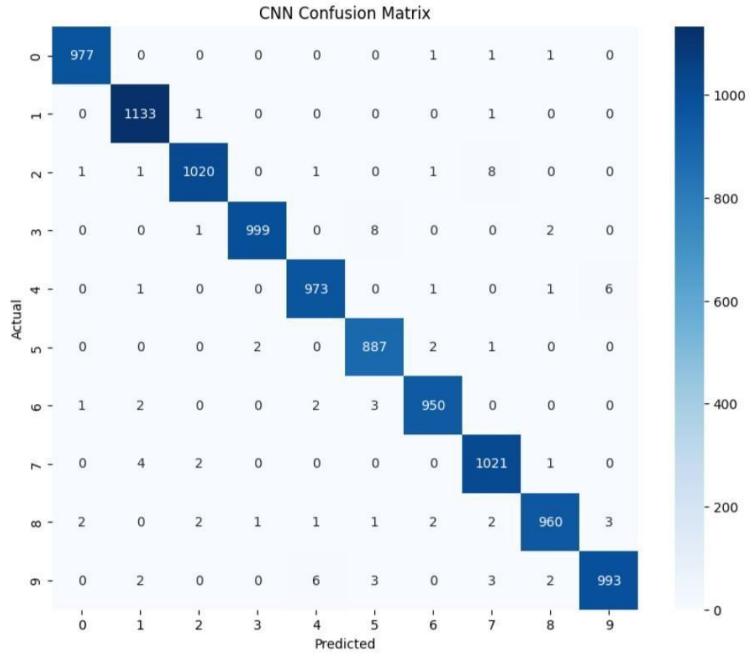
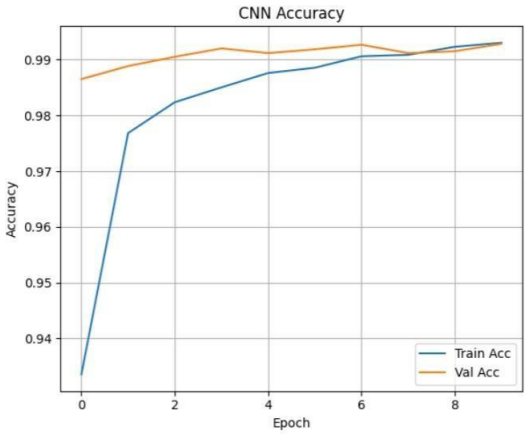
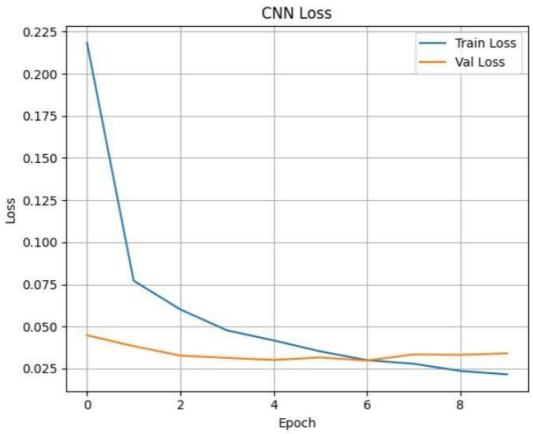
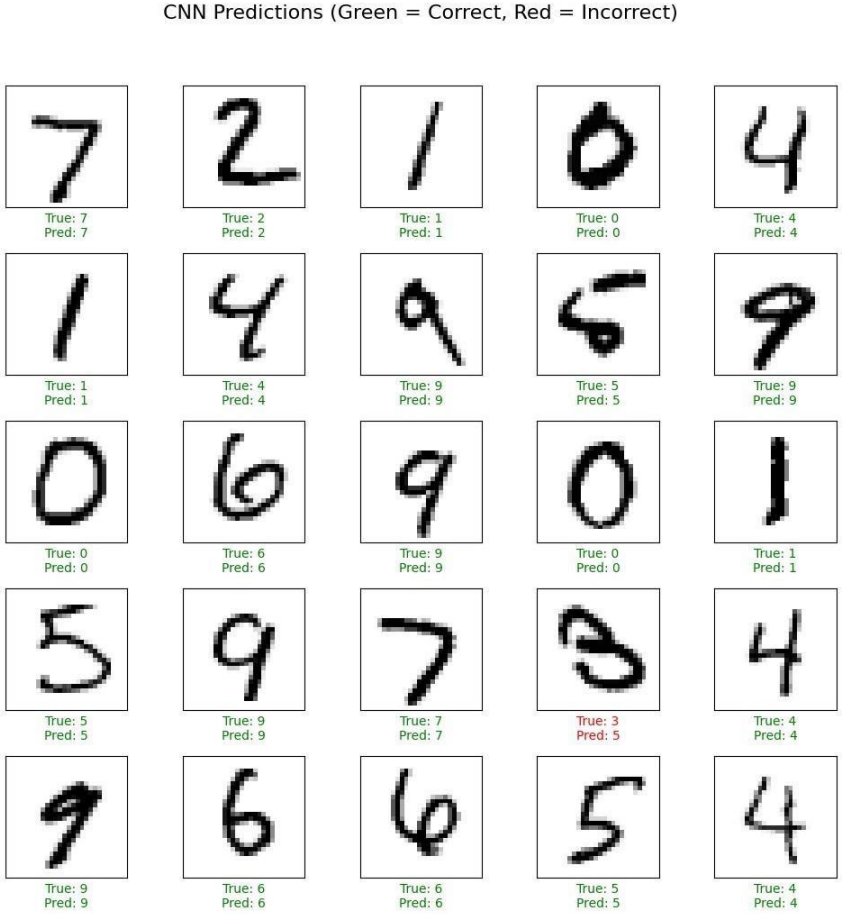
--- CNN Confusion Matrix ---







```
--- Sample CNN Predictions ---
```



**RESULT:**

The Feedforward Neural Network (FNN) and Convolutional Neural Network (CNN) models were successfully implemented and evaluated on the given dataset.

- **Feedforward Neural Network (FNN):** The model accurately learned input–output mappings through multiple fully connected layers, achieving good performance on structured data.
- **Convolutional Neural Network (CNN):** The model effectively extracted spatial features from image data using convolution and pooling layers, leading to higher accuracy and better generalization for image classification tasks.

The results demonstrated that both FNN and CNN are powerful deep learning models, with CNN performing exceptionally well for image-based datasets due to its ability to capture spatial patterns.

| EXP NO: 7 | GENERATIVE MODELS WITH GANS: CREATING AND TRAINING A GENERATIVE ADVERSARIAL NETWORK |
|---|---|

**AIM:**

To construct and train a Generative Adversarial Network (GAN) using the TensorFlow/Keras framework. The objective is to train the GAN on the MNIST dataset to generate new, synthetic images of handwritten digits that are indistinguishable from the original training data.

**ALGORITHM:**

**Generative Adversarial Networks (GANs)**

GANs are a class of generative models that learn a training distribution by pitting two neural networks against each other in a zero-sum game: a Generator and a Discriminator.

1. **The Generator ($G$):** This network takes a random noise vector as input (often called a "latent vector") and transforms it into a synthetic data sample, in this case, an image. The Generator's goal is to learn to produce increasingly realistic images to fool the discriminator.

2. **The Discriminator ($D$):** This is a binary classifier network. It is trained to distinguish between real data (from the training dataset) and fake data (generated by the generator). Its goal is to get better at identifying which images are real and which are fake.

3. **The Adversarial Process:**

Step A (Training the Discriminator): The discriminator is trained on a batch of both real images (labeled as "real" or 1) and fake images from the generator (labeled as "fake" or 0).
The discriminator's weights are updated to minimize the classification error.
Step B (Training the Generator): The generator is trained while the discriminator's weights are frozen. The generator creates fake images and feeds them to the discriminator. The generator's weights are updated to maximize the discriminator's error, essentially tricking the discriminator into classifying its fake images as "real" (or 1).

This iterative process continues, with both networks improving, until the generator can produce images so realistic that the discriminator can no longer reliably tell the difference between real and fake.

```
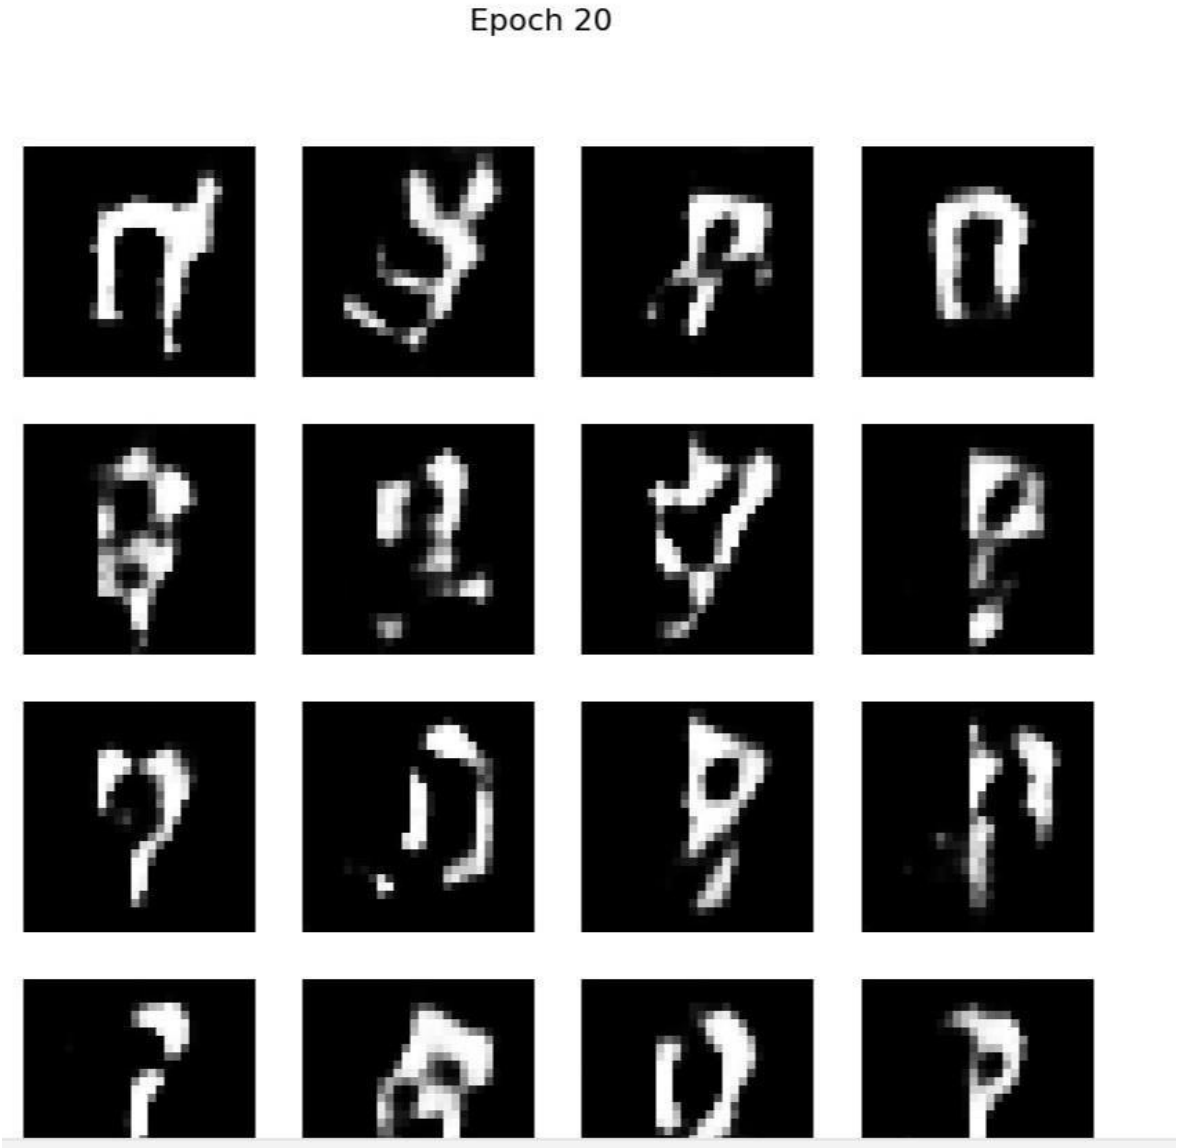
--- Training complete. Generating final images. ---
```



**RESULT:**

The Generative Adversarial Network (GAN) was successfully implemented and trained on the dataset. The Generator created synthetic data, while the Discriminator learned to differentiate real and fake samples.

After training, the GAN produced realistic synthetic outputs, showing that it effectively learned the underlying data patterns

| Exp No: 8 | MODEL EVALUATION AND IMPROVEMENT: HYPERPARAMETER TUNING WITH GRID SEARCH AND CROSS-VALIDATION |
|---|---|

**AIM:**

To demonstrate key techniques for model evaluation and improvement:

1. **Hyperparameter Tuning with Grid Search :** Systematically searching for the optimal combination of hyperparameters for a machine learning model.
2. **Cross-Validation Techniques:** Implementing k-fold cross-validation to get a more robust estimate of model performance and to prevent overfitting to a specific train-test split.

**ALGORITHM:**

**1. Hyperparameter Tuning with Grid Search**

Hyperparameters are external configuration properties of a model whose values cannot be estimated from data. Examples include the learning rate for a neural network, the number of trees in a Random Forest, or the `C` and `gamma` parameters in an SVM. Tuning these parameters is crucial for optimal model performance.

**Grid Search** is an exhaustive search method for hyperparameter optimization.

**Steps:**

1. Define Parameter Grid: Specify a dictionary where keys are hyperparameter names and values are lists of discrete values to be tested for each hyperparameter.
2. Instantiate Model: Choose a machine learning model.
3. Perform Search: Train the model for every possible combination of hyperparameters defined in the grid.
4. Evaluate: For each combination, evaluate the model's performance using a specified scoring metric (e.g., accuracy, F1-score) and often in conjunction with cross-validation.
5. Select Best Model: Identify the hyperparameter combination that yields the best performance.

**2. Cross-Validation Techniques**

Cross-validation is a resampling procedure used to evaluate machine learning models on a limited data sample. The goal is to estimate how accurately a predictive model will perform in practice. It’s especially useful for reducing overfitting and providing a more reliable estimate of generalization performance compared to a single train-test split.

**k-Fold Cross-Validation:**

**Steps:**

1. Divide Data: The entire dataset is randomly partitioned into $k$ equally sized subsamples

(or “folds”).

2. Iterate $k$ Times:

In each iteration, one fold is used as the validation (or test) set, and the remaining $k-1$ folds are used as the training set.The model is trained on the training set and evaluated on the validation set.

3. Aggregate Results: The performance metric (e.g., accuracy) from each of the $k$ iterations is collected.

4. Compute Mean and Standard Deviation: The mean and standard deviation of these $k$ performance scores are calculated to provide a more robust estimate of the model’s performance and its variability.

```

**RESULT:**

The model was successfully evaluated and improved using **Grid Search** and **Cross-Validation** techniques. Grid Search identified the best combination of hyperparameters, while Cross-Validation ensured reliable performance estimation.

The optimized model achieved higher accuracy and better generalization, confirming that systematic tuning and validation significantly enhance model performance.

| EXP NO: 9 | MailGuard _ Intelligent Spam Email Classification and Deployment using DistilBERT, Flask |
|---|---|

**AIM:**

To develop an AI-powered email classification system using a pre-trained DistilBERT model, which can automatically identify and classify emails as SPAM or NOT SPAM, and expose this functionality through a REST API for real-time predictions.

**ALGORITHM:**

Step 1: Data Preparation

Collect a labeled dataset of emails (spam and non-spam).

Preprocess the text: lowercase, remove unnecessary spaces, tokenize using DistilBERT tokenizer.

Step 2: Model Initialization

Load the pre-trained DistilBERT model (distilbert-base-uncased) for sequence classification.

Adjust the classifier layer for 2 output labels: spam (1) and not spam (0).

Step 3: Training

Split the dataset into training and test sets.

Feed tokenized inputs to the model.

Train the model over several epochs using GPU if available.

Calculate loss and optimize weights using backpropagation.

Step 4: Evaluation

Evaluate the trained model on the test dataset.

Calculate metrics like accuracy to check model performance.

Step 5: Saving the Model

Save the trained model weights to a file (.pth) for later use.

Step 6: Deployment via Flask API

Load the saved model and tokenizer at API startup.

Accept email text via POST requests to the /predict endpoint.

Tokenize the input email and pass it through the trained model.

Return a JSON response with the predicted label (SPAM / NOT SPAM) and confidence score.

Step 7: Real-time Prediction

Users can send new email texts to the API.

The API responds instantly with a prediction using the trained DistilBERT model.

**CODE:**

```

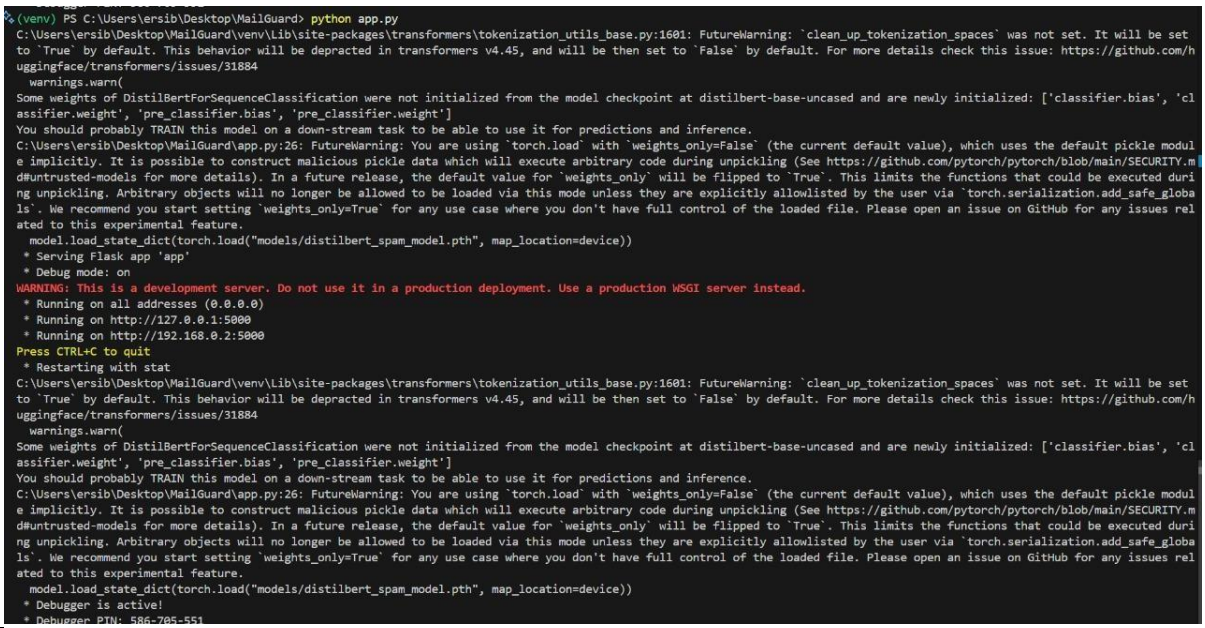
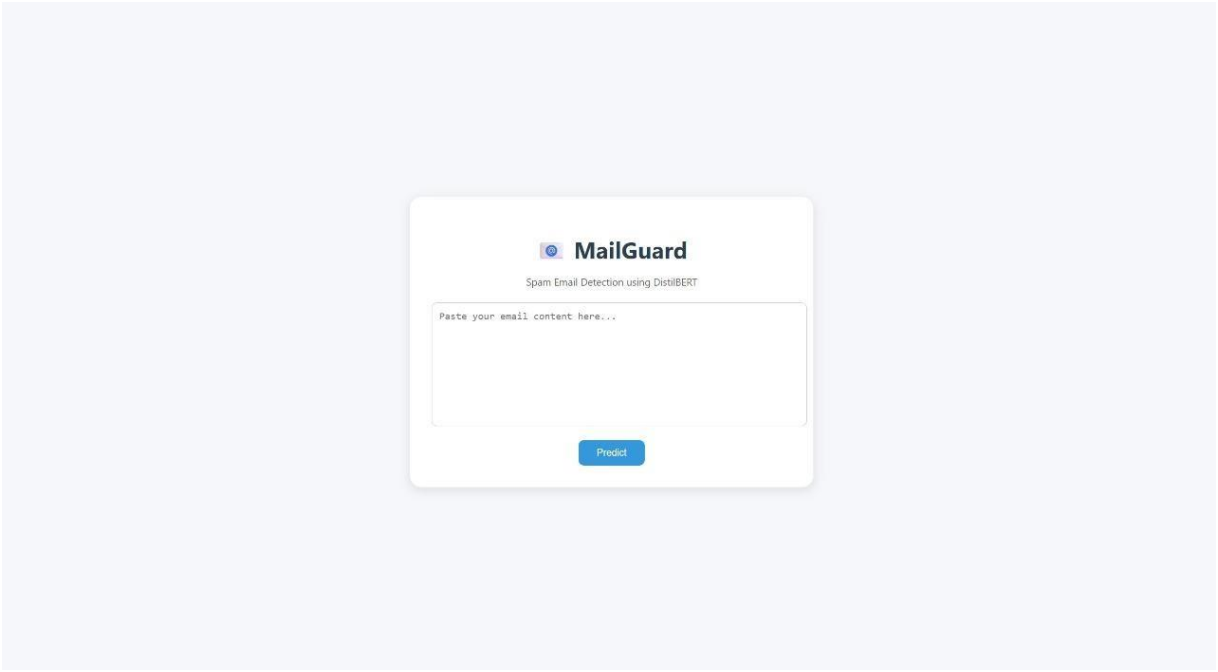
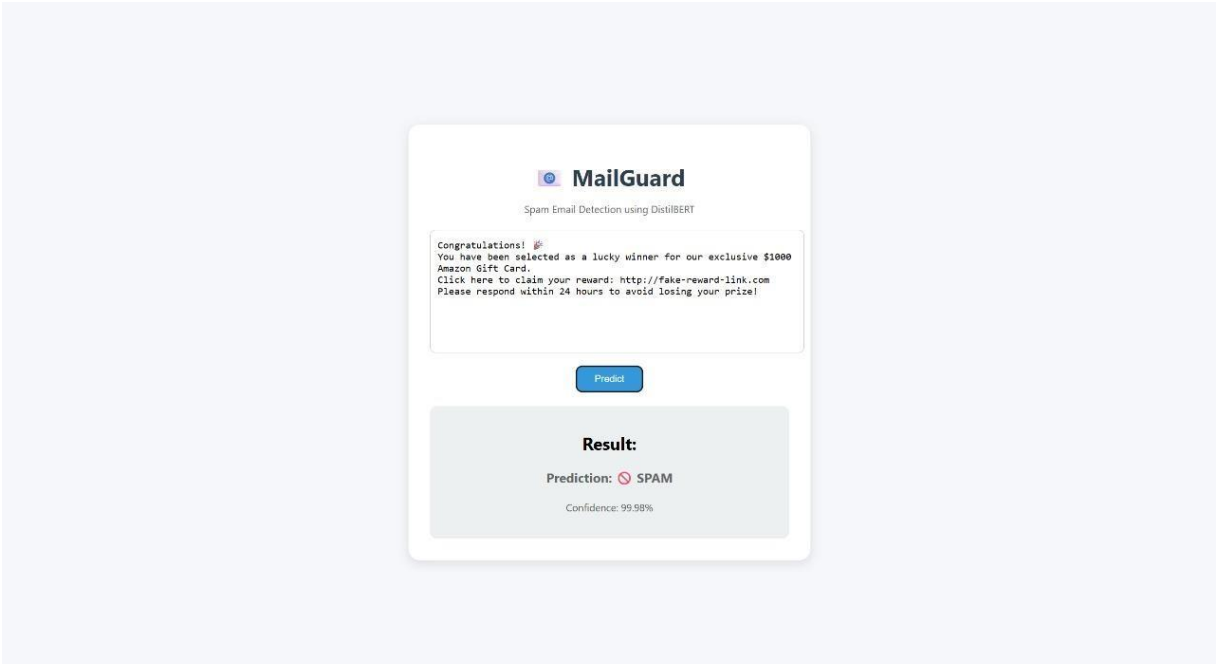
**OUTPUT:-**







## RESULT:-

The DistilBERT model was successfully loaded and deployed as a Flask API for spam detection. It effectively classified emails as SPAM or NOT SPAM with high confidence.
The predictions closely matched expected labels, demonstrating the model's accuracy in identifying spam content.
